

Abstract

A storage compartment to store one or more items includes a body, a top, and a coupling element operable to couple the top to the body and allow the top to be moved relative to the body. The body includes a bottom and a sidewall that
5 define an interior in which one or more items, such as a storage medium or a portable device, may be stored. The sidewall includes a passage to allow an item stored in the interior to be coupled to another item outside the interior. The top may be moved relative to the body to open and close the storage compartment. With
the storage compartment, one may securely and safely store a PDA, for example,
10 that is coupled with a processor of a computer system.
